

# **Contents: Game Playing (Minimax, alpha-beta pruning)**

## **Brief about Constraint Satisfaction Problem**

# Board Games

---

- Two Person
  - Have exactly two players.
- Zero Sum
  - In zero sum games, the payoff is zero. One player's gain is the other player's loss. One wins; the other loses.
- Complete Information
  - Both players have access to all the information i.e., can see the board, and thus know the options the other play has.
- Alternate moves
  - Players take turns to make their moves.

# What kind of games

Mainly games of strategy with the following characteristics:

1. Sequence of **moves** to play
2. Rules that specify **possible moves**
3. Rules that specify a **payment** for each move
4. Objective is to **maximize** your payment

# Games vs Search Problem

- **Unpredictable opponent** → specifying a move for every possible opponent reply
- **Time limits** → unlikely to find goal, must approximate

# Games as Adversarial Search

- **States:**
  - board configurations
- **Initial state:**
  - the board position and which player will move
- **Successor function:**
  - returns list of (move, state) pairs, each indicating a legal move and the resulting state
- **Terminal test:**
  - determines when the game is over
- **Utility function:**
  - gives a numeric value in terminal states  
(e.g., -1, 0, +1 for loss, tie, win)

# Game Tree (2-player, Deterministic, Turns)

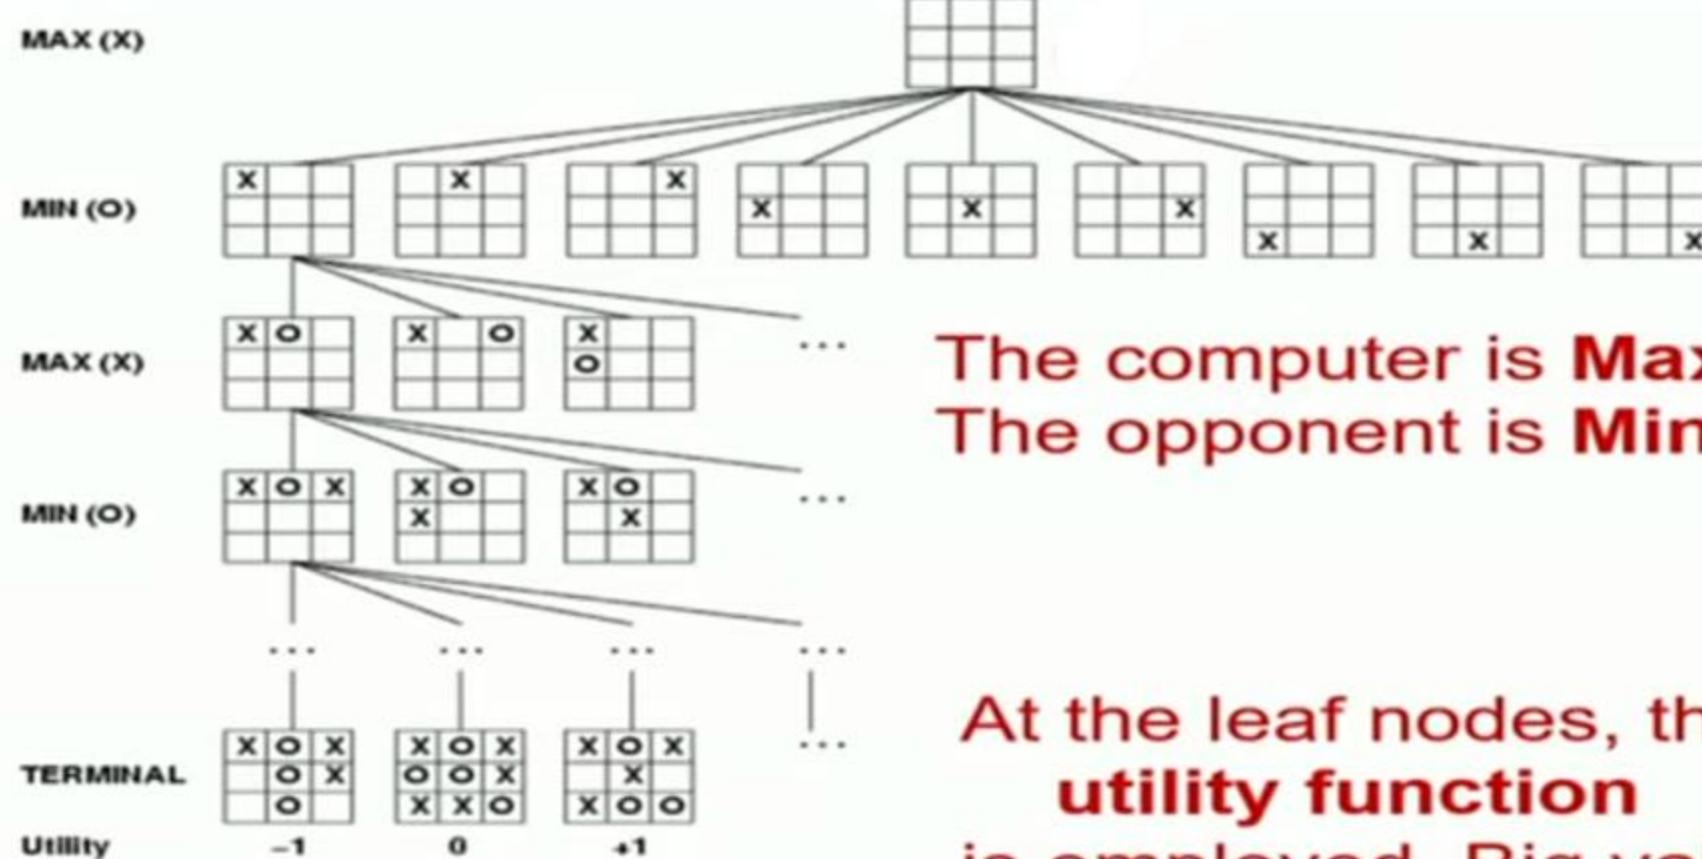

computer's turn

opponent's turn

computer's turn

opponent's turn

leaf nodes are evaluated

The computer is **Max**.  
The opponent is **Min**.

At the leaf nodes, the **utility function** is employed. Big value means good, small is bad.

# Game Trees

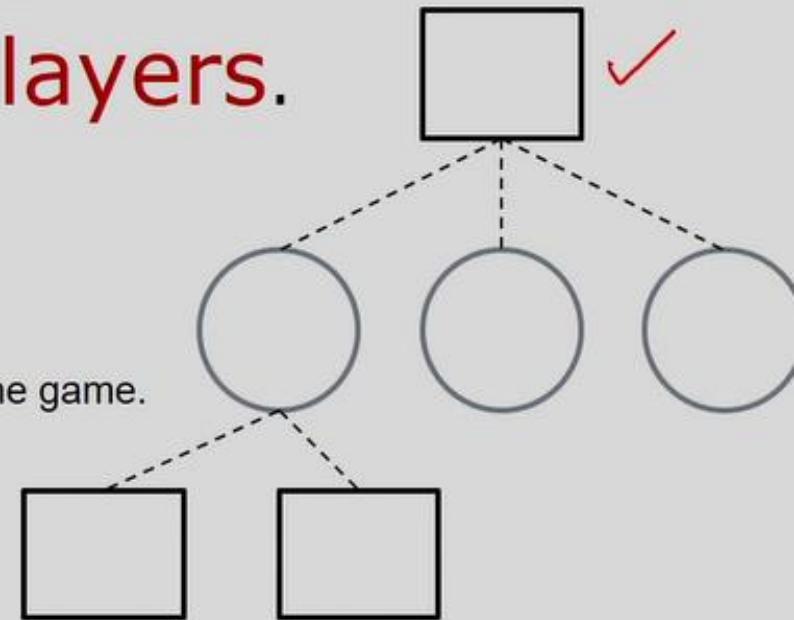

---

- A game is represented by a game tree.
  - Game tree is a layered tree in which at each alternating level, one or the other player makes the choice.
  - Layers - MAX layers and the MIN layers.

A game starts at the root with MAX playing first.

Leaves of a game tree are labelled with outcome of the game.

The game ends at the leaf nodes.

# Minimax Procedure

---

- For complex games such as chess or checkers, search to termination is out of question.

Complete game tree for chess has approximately  $10^{40}$  nodes.

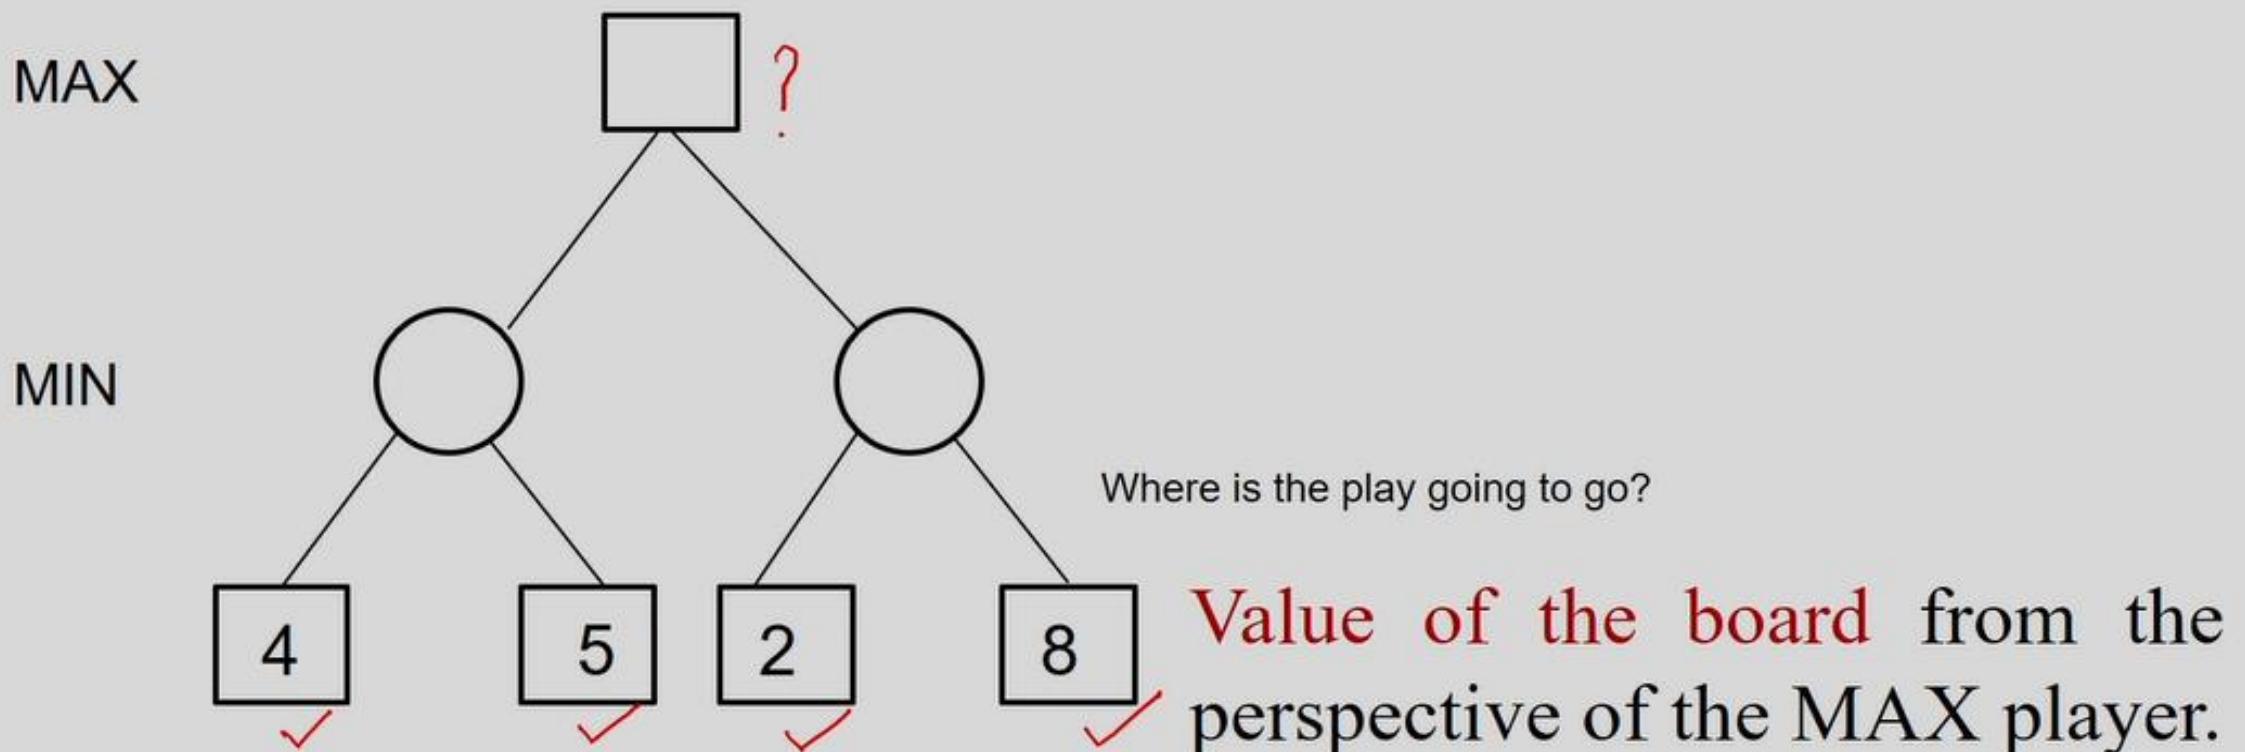

Even for a game as simple as Tic-tac-toe there are over 3,50,000 nodes in the complete game tree.

## □ Good First Move?

- A good first move can be extracted by a procedure called the Minimax.
- This estimate can be made by applying a static evaluation function to the leaf node.
- Back-up values level by level.
  - ✓ MAX parent of MIN nodes is assigned backed-up value equal to maximum of the evaluations of the nodes.
  - MIN parent of MAX nodes is assigned the minimum.

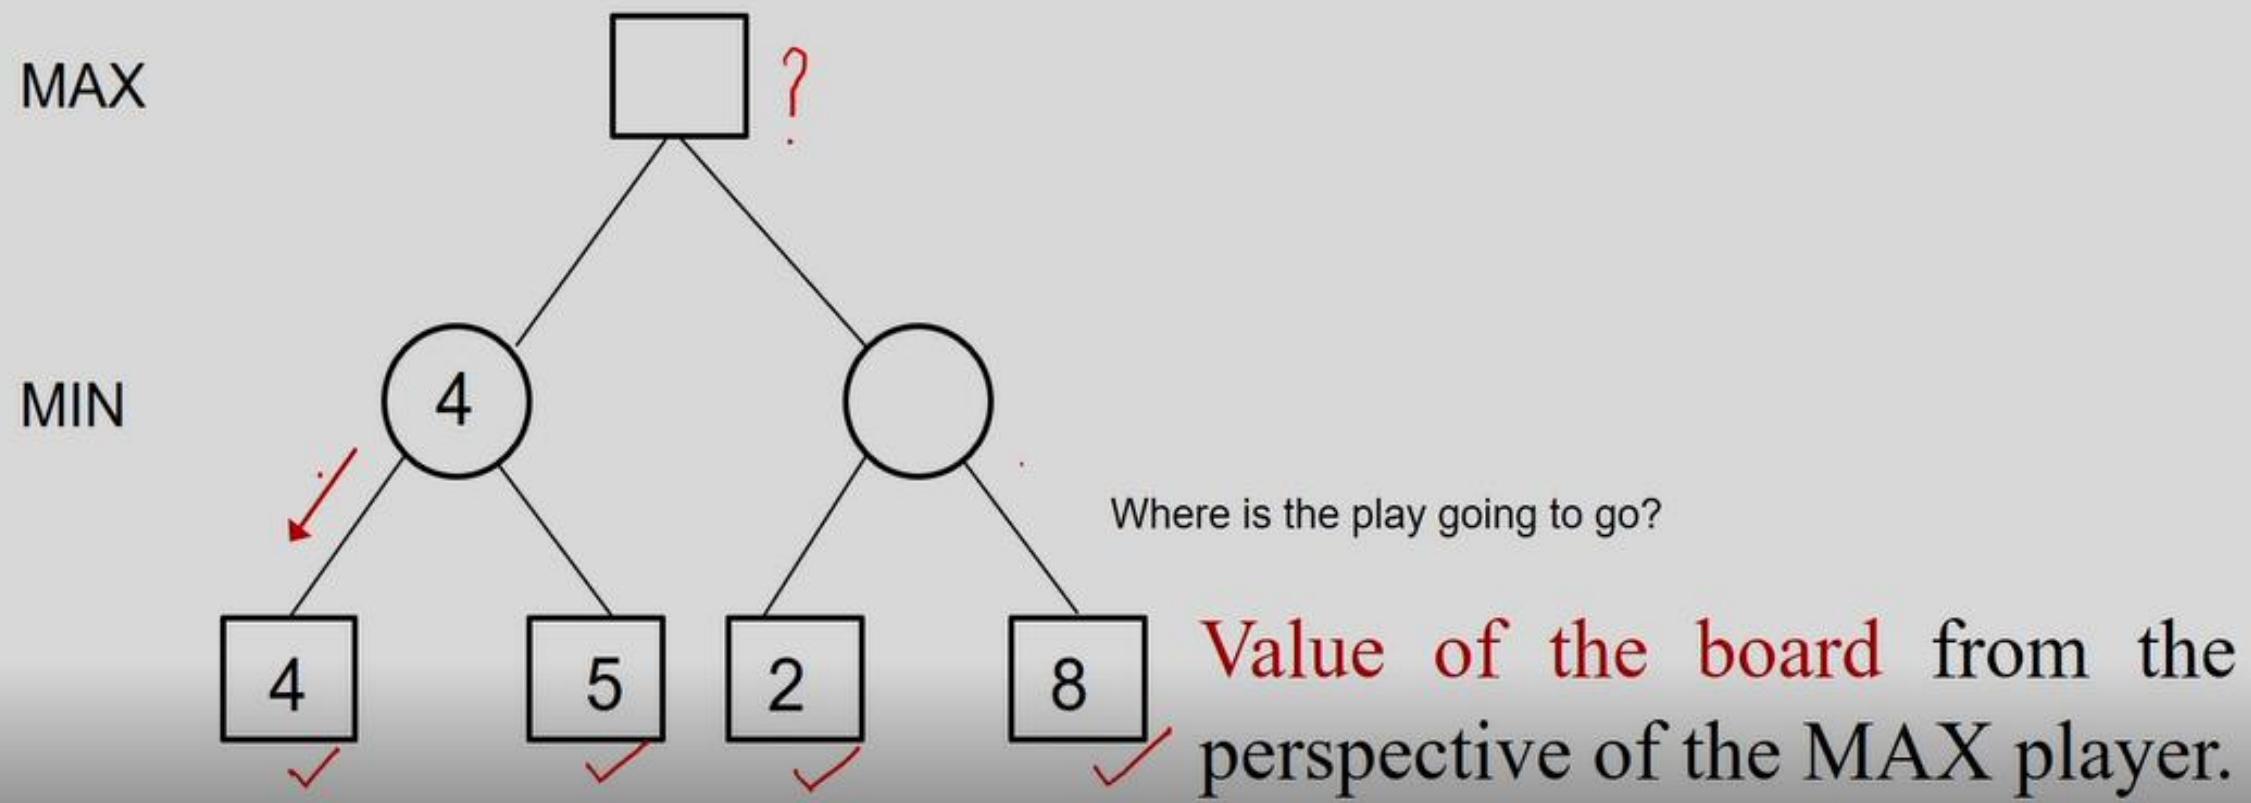

# Minimax Procedure

---

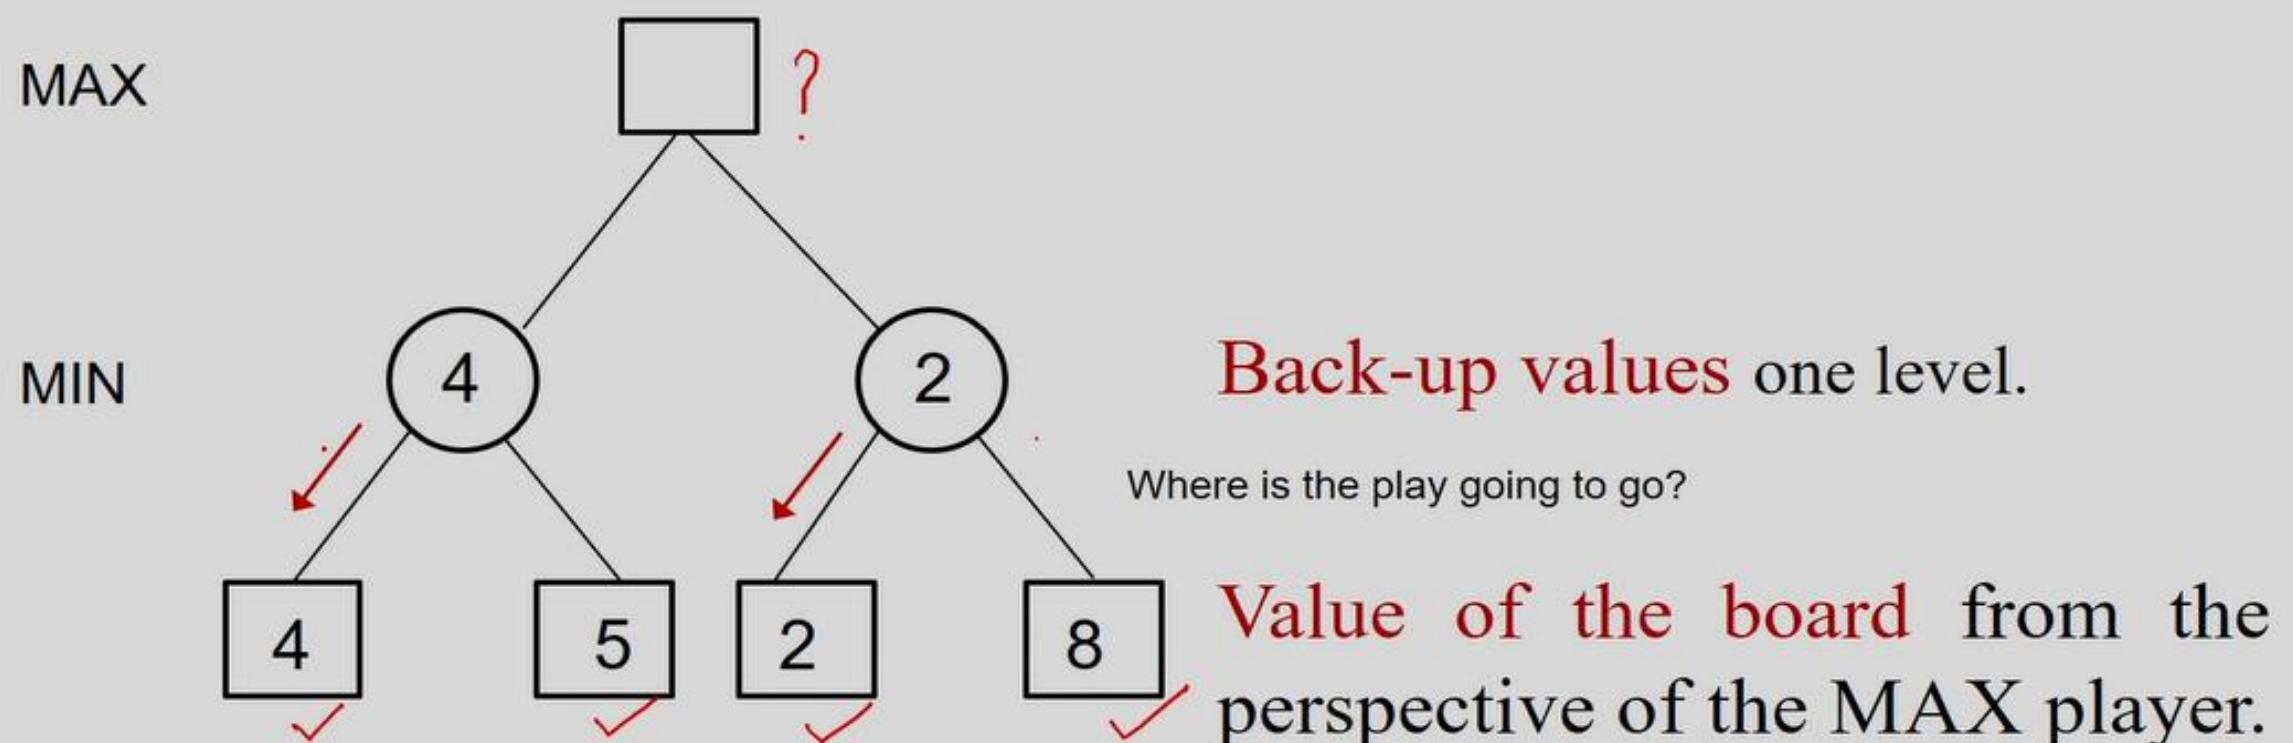

# Minimax Procedure

---

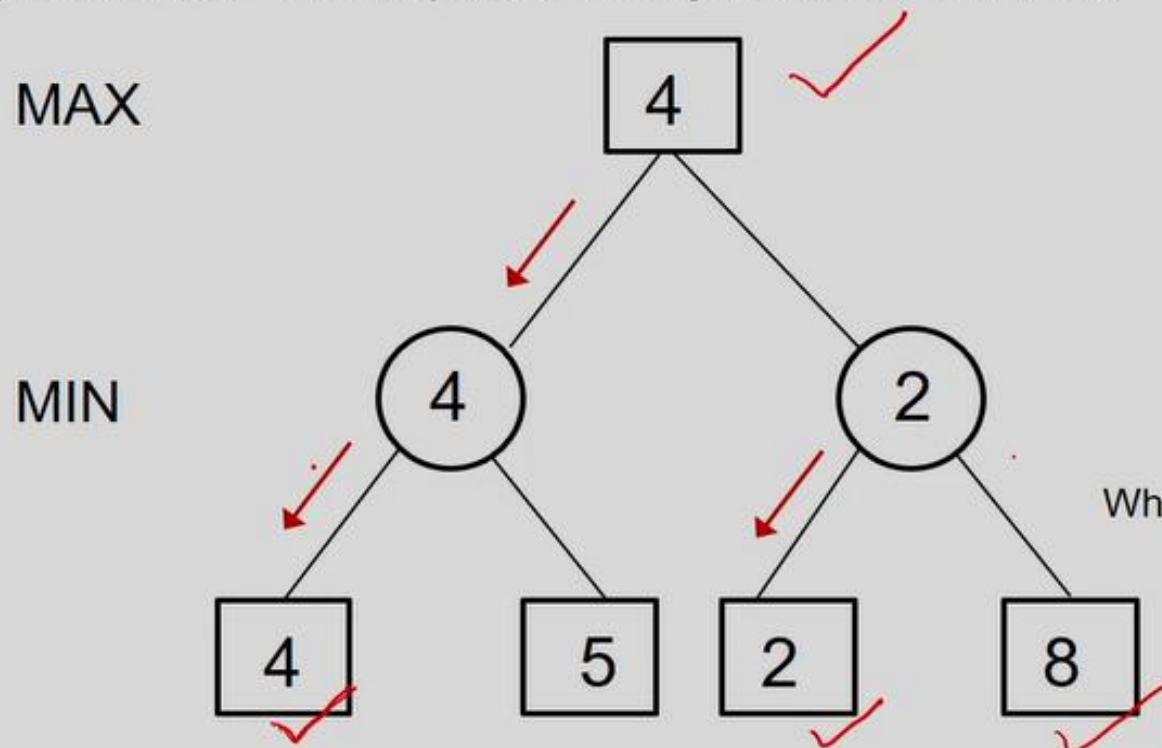

# Minimax Procedure

# Minimax Procedure

Static evaluation functions measures the worth of a leaf node.

Measurement is based on features thought to influence the worth.  
E.g. In checkers – relative piece advantage; control of center etc.

Adversarial game – Competing with each other.

Far shorter than 8, the MAX player wanted.  
More than 2 that the MIN player wanted.

## Minimax Algorithm

1. Go to the **bottom** of the tree.
- ✓ 2. Compute **static values**.
3. Back them up level-by-level.
4. Decide where to go.

**Back-up values** one level.

Where is the play going to go?

**Value of the board** from the perspective of the MAX player.

Do not expect to go where YOU wanted!

# Minimax Algorithm

**function** MINIMAX-DECISION(*state*) **returns** an action

*v*  $\leftarrow$  MAX-VALUE(*state*)

**return** the *action* in SUCCESSORS(*state*) with value *v*

---

**function** MAX-VALUE(*state*) **returns** a utility value

**if** TERMINAL-TEST(*state*) **then return** UTILITY(*state*)

*v*  $\leftarrow -\infty$

**for** *a, s* in SUCCESSORS(*state*) **do**

*v*  $\leftarrow$  MAX(*v*, MIN-VALUE(*s*))

**return** *v*

---

**function** MIN-VALUE(*state*) **returns** a utility value

**if** TERMINAL-TEST(*state*) **then return** UTILITY(*state*)

*v*  $\leftarrow \infty$

**for** *a, s* in SUCCESSORS(*state*) **do**

*v*  $\leftarrow$  MIN(*v*, MAX-VALUE(*s*))

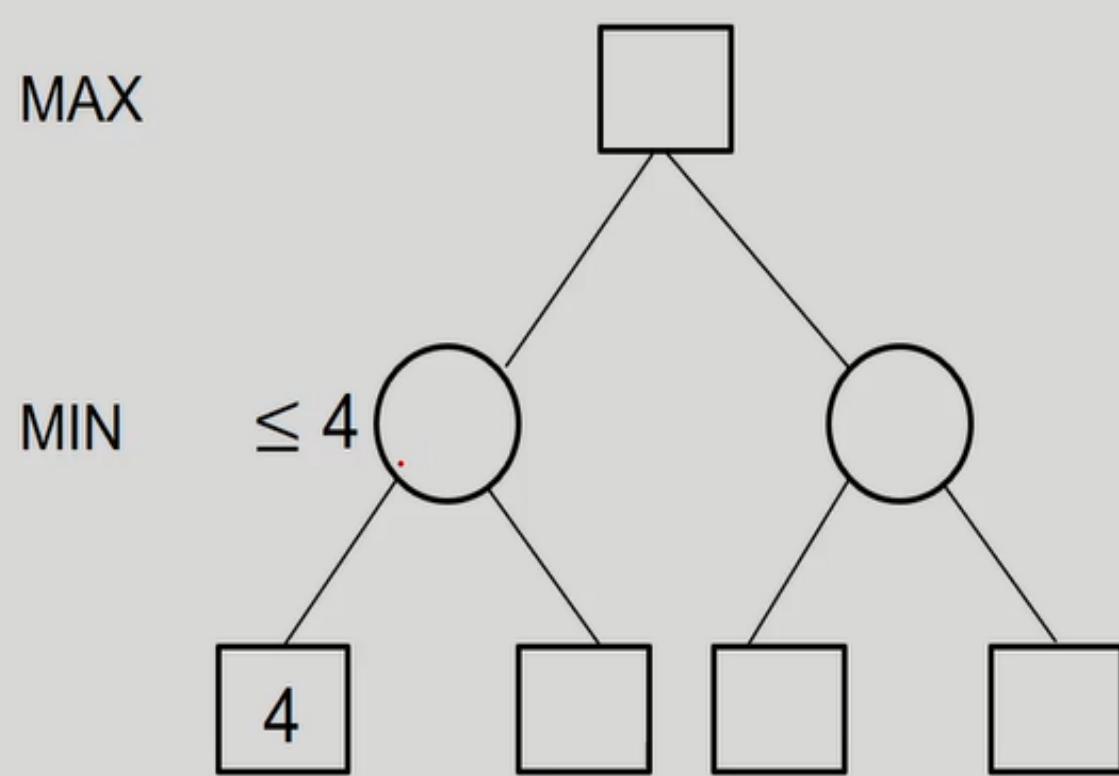

**return** *v*

---

# Properties of Minimax

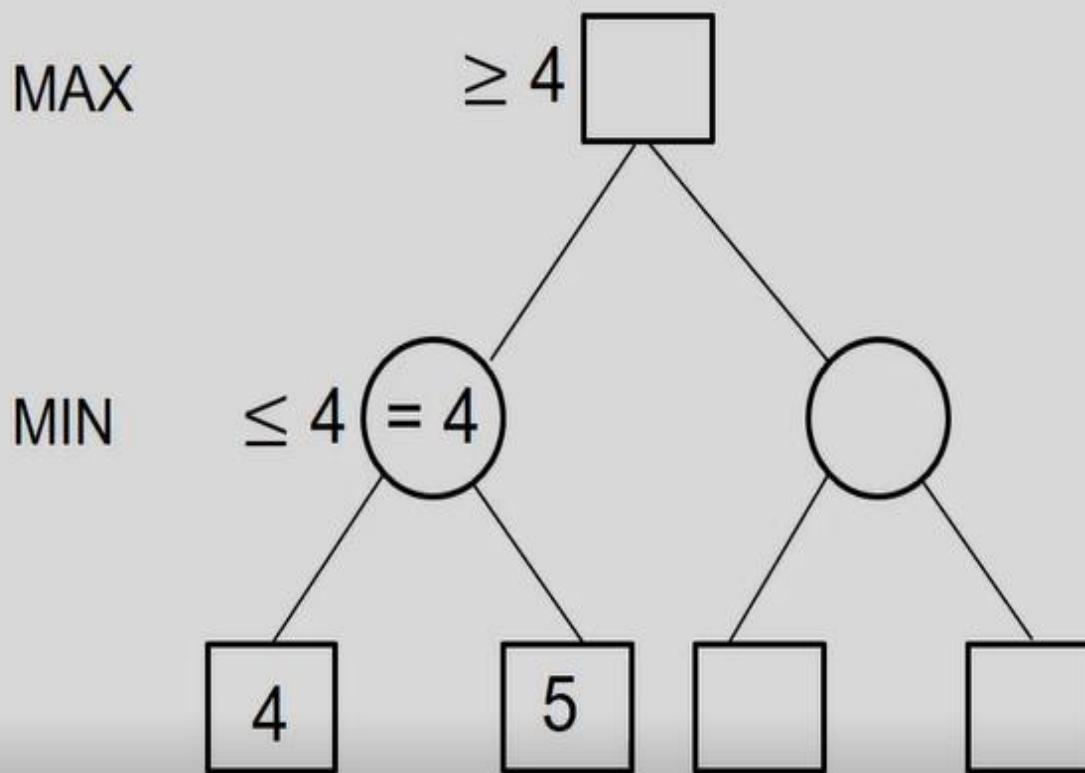

- Complete?
  - Yes (if tree is finite)
- Optimal?
  - Yes (against an optimal opponent)
  - No (does not exploit opponent weakness against suboptimal opponent)
- Time complexity?
  - $O(b^m)$
- Space complexity?
  - $O(bm)$  (depth-first exploration)

# Alpha-beta Pruning

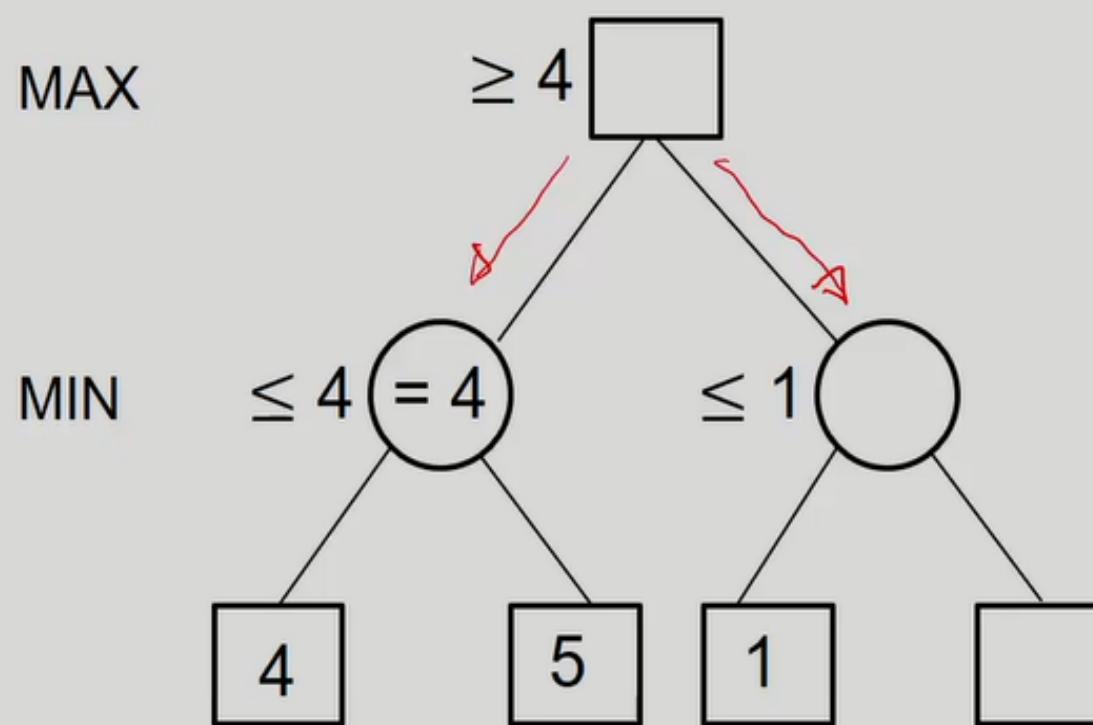

Compute static values one at a time.

# Alpha-beta Pruning

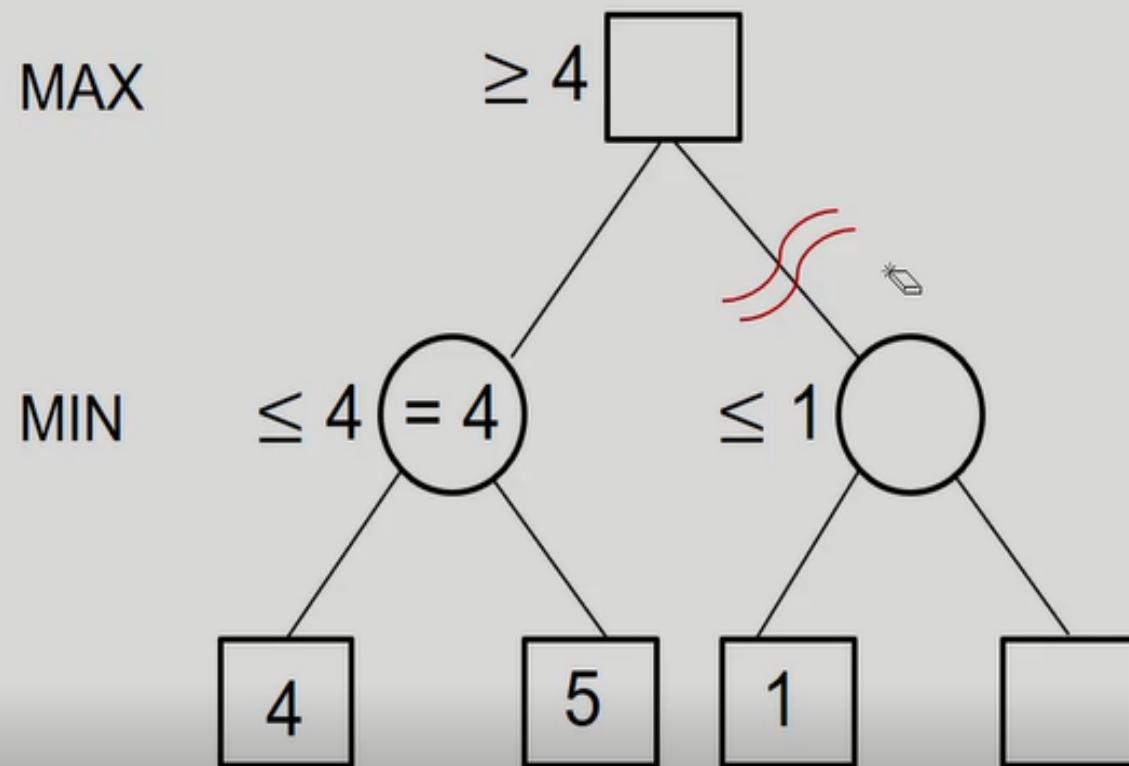

Compute static values one at a time.

# Alpha-beta Pruning

Compute static values one at a time.

# Alpha-beta Pruning

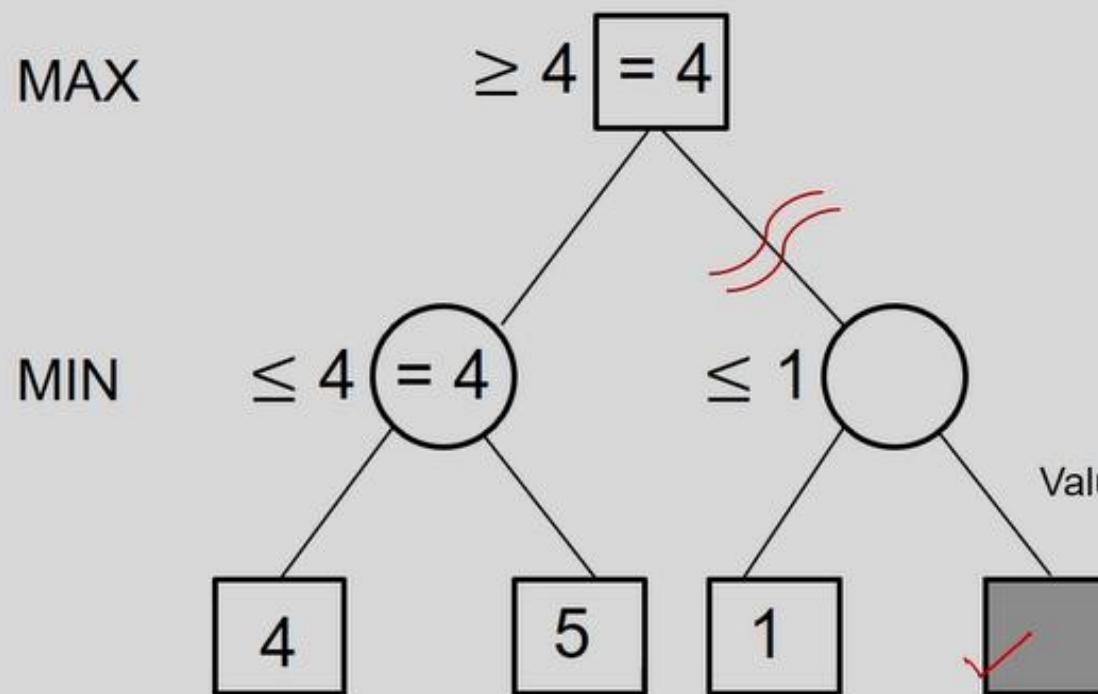

Compute static values one at a time.

# Alpha-beta Pruning

## Alpha-beta Algorithm

1. Not a separate algorithm!
2. Layering on top of Minimax.

Essence of Alpha-Beta Pruning;  
cuts out sections of the search space

Values in the cut-out branch can't affect the value of the root node.

Compute static values one at a time.

We don't need to compute the value at this node.

# Alpha-beta Pruning

---

- Alpha-beta pruning is not actually a new algorithm, rather an optimization technique for minimax algorithm.
- It reduces the computation time by a huge factor. This allows us to search much faster and even go into deeper levels in the game tree.
- It cuts off branches in the game tree which need not be searched because there already exists a better move available.
- It is called Alpha-Beta pruning because it passes two extra parameters in the minimax function

# Alpha-beta Pruning

---

Traverse the search tree in depth-first order

- ✓ **alpha(n)** The best value that MAX currently can guarantee; maximum value found so far.
- ✓ **beta(n)** The best value that MIN currently can guarantee; minimum value found so far

## □ Beta cutoff

Cutoff- Do not generate or examine any more of n's children.

Given a MAX node n

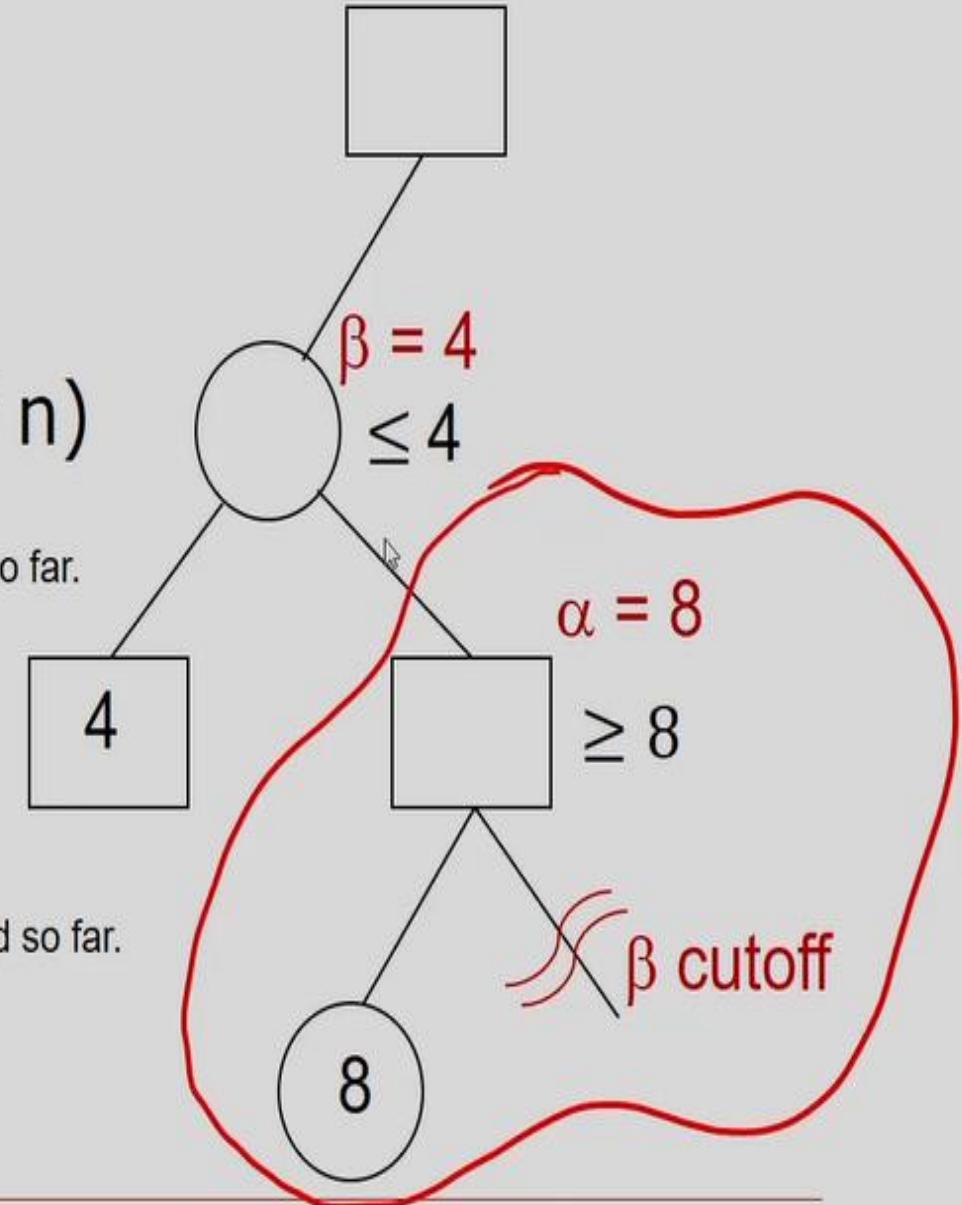

Cutoff ~~search~~ below n

if  $\alpha(n) \geq \beta(i)$

(for some MIN node ancestor i of n)

beta - best value that MIN currently can guarantee; minimum value found so far.

alpha - best value that MAX currently can guarantee; maximum value found so far.

## □ Alpha cutoff

Cutoff- Do not generate or examine any more of n's children.

Given a MIN node  $n$

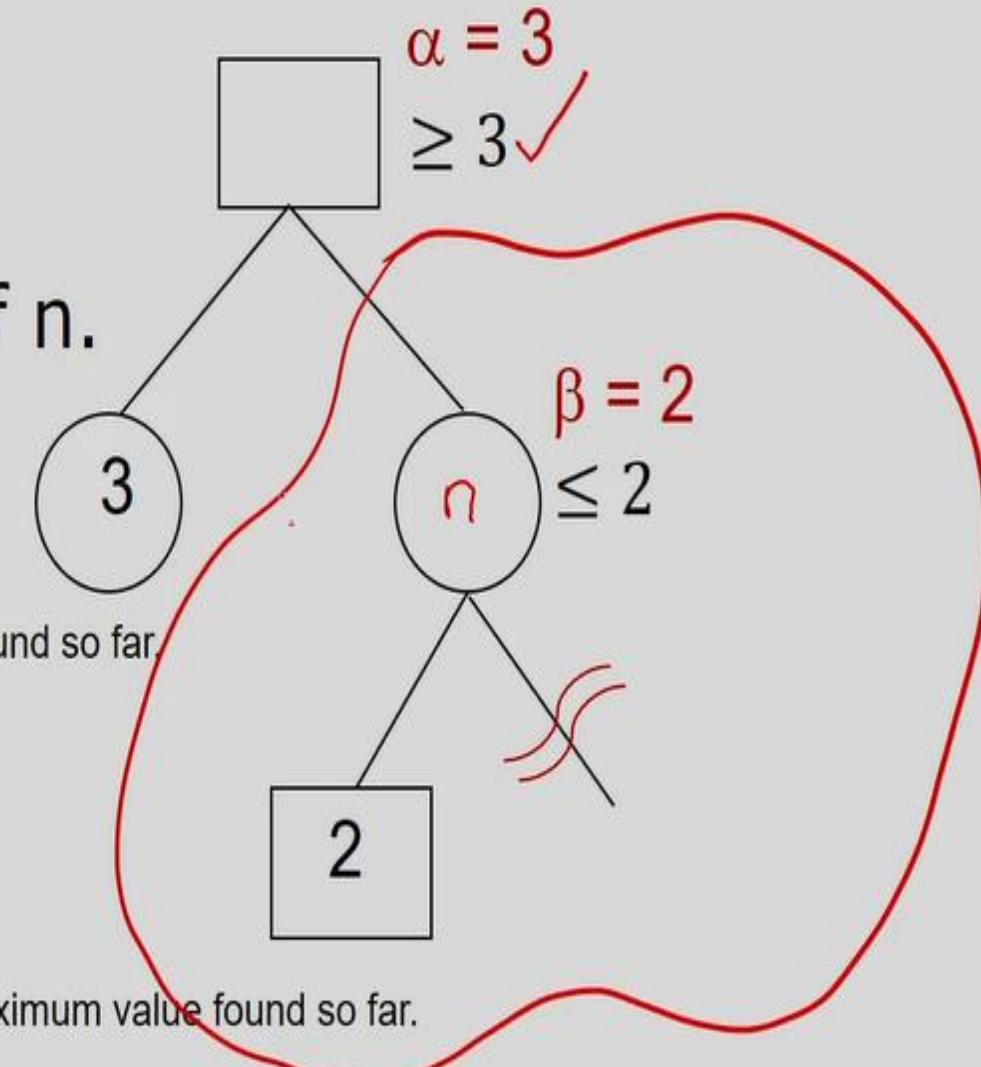

Cutoff search below  $n$

✓ if  $\text{beta}(n) \leq \text{alpha}(i)$

for some MAX node ancestor  $i$  of  $n$ .

beta - best value that MIN currently can guarantee; minimum value found so far

alpha - best value that MAX currently can guarantee; maximum value found so far.

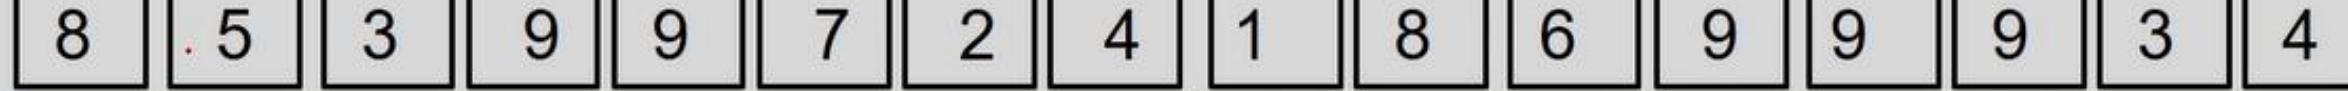

# Alpha-beta Pruning

# Algorithm for alpha beta pruning

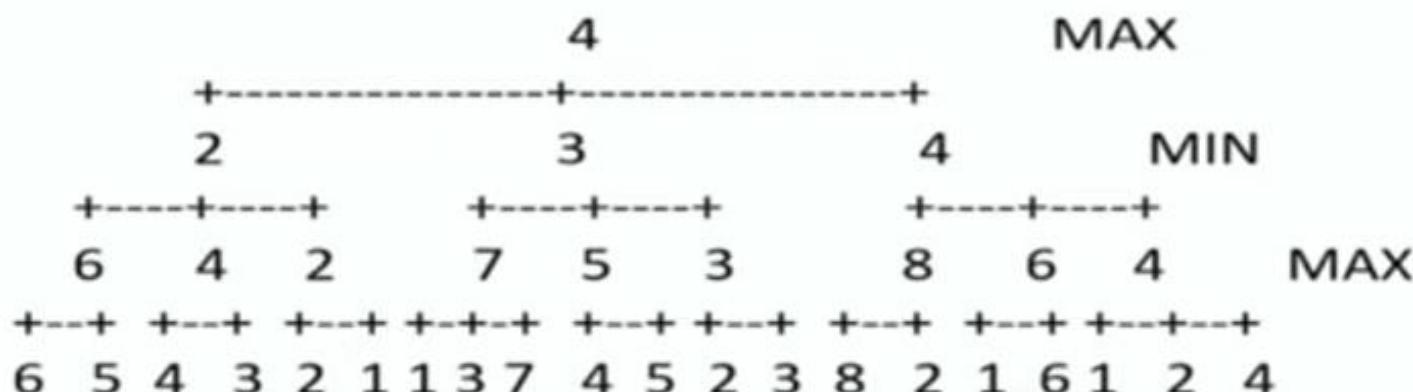

```
evaluate (node, alpha, beta)
    if node is a leaf
        return the heuristic value of node

    if node is a minimizing node
        for each child of node
            beta = min (beta, evaluate (child, alpha, beta))
        if beta <= alpha
            return beta
    return beta

    if node is a maximizing node
        for each child of node
            alpha = max (alpha, evaluate (child, alpha, beta))
        if beta <= alpha
            return alpha
    return alpha
```

## Bad and Good Cases for Alpha-Beta Pruning

- Bad: Worst moves encountered first

- Good: Good moves ordered first

- If we can order moves, we can get more benefit

Let  $T(m)$  be time complexity of search for depth  $m$

Normally:

$$T(m) = b.T(m-1) + c \rightarrow T(m) = O(b^m)$$

With ideal  $\alpha$ - $\beta$  pruning:

$$T(m) = T(m-1) + (b-1)T(m-2) + \cancel{c} \rightarrow T(m) = O(b^{m/2})$$

## Properties of $\alpha$ - $\beta$

- Pruning **does not** affect final result. This means that it gets the exact same result as does full minimax.
- Good move ordering improves effectiveness of pruning
- With "perfect ordering," time complexity =  $O(b^{m/2})$

## Constraint satisfaction problems (CSPs)

Standard search problem:

state is a “black box”—any old data structure  
that supports goal test, eval, successor

CSP:

state is defined by variables  $X_i$  with values from domain  $D_i$

goal test is a set of constraints specifying  
allowable combinations of values for subsets of variables

Simple example of a formal representation language

Allows useful general-purpose algorithms with more power  
than standard search algorithms

## Example: Map-Coloring

Variables  $WA, NT, Q, NSW, V, SA, T$

Domains  $D_i = \{\text{red}, \text{green}, \text{blue}\}$

Constraints: adjacent regions must have different colors

$WA \neq NT$  (if the language allows this), or

$(WA, NT) \in \{(\text{red}, \text{green}), (\text{red}, \text{blue}), (\text{green}, \text{red}), (\text{green}, \text{blue})\}$

## Example: Map-Coloring contd.

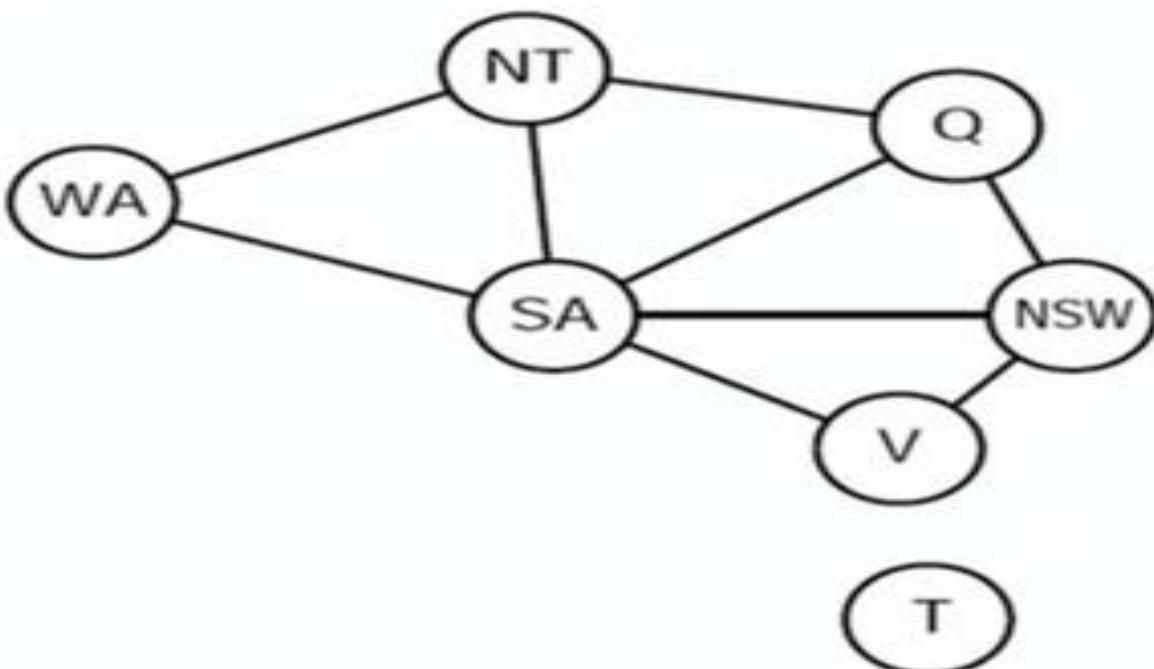

Solutions are assignments satisfying all constraints, e.g.,

{ WA = red, NT = green, Q = red, NSW = green, V = red, SA = blue }

## Constraint graph

Binary CSP: each constraint relates at most two variables

Constraint graph: nodes are variables, arcs show constraints

Tasmania is an independent subproblem!

## Varieties of CSPs

### Discrete variables

finite domains; size  $d \Rightarrow O(d^n)$  complete assignments

- ◊ e.g., Boolean CSPs, incl. Boolean satisfiability (NP-complete)

infinite domains (integers, strings, etc.)

- ◊ e.g., job scheduling, variables are start/end days for each job
- ◊ need a constraint language, e.g.,  $Start.Job_1 + 5 \leq Start.Job_3$
- ◊ linear constraints solvable, nonlinear undecidable

### Continuous variables

- ◊ e.g., start/end times for Hubble Telescope observations
- ◊ linear constraints solvable in poly time by LP methods

## Varieties of constraints

Unary constraints involve a single variable,

e.g.,  $SA \neq green$

Binary constraints involve pairs of variables,

e.g.,  $SA \neq WA$

Higher-order constraints involve 3 or more variables,

e.g., cryptarithmetic column constraints

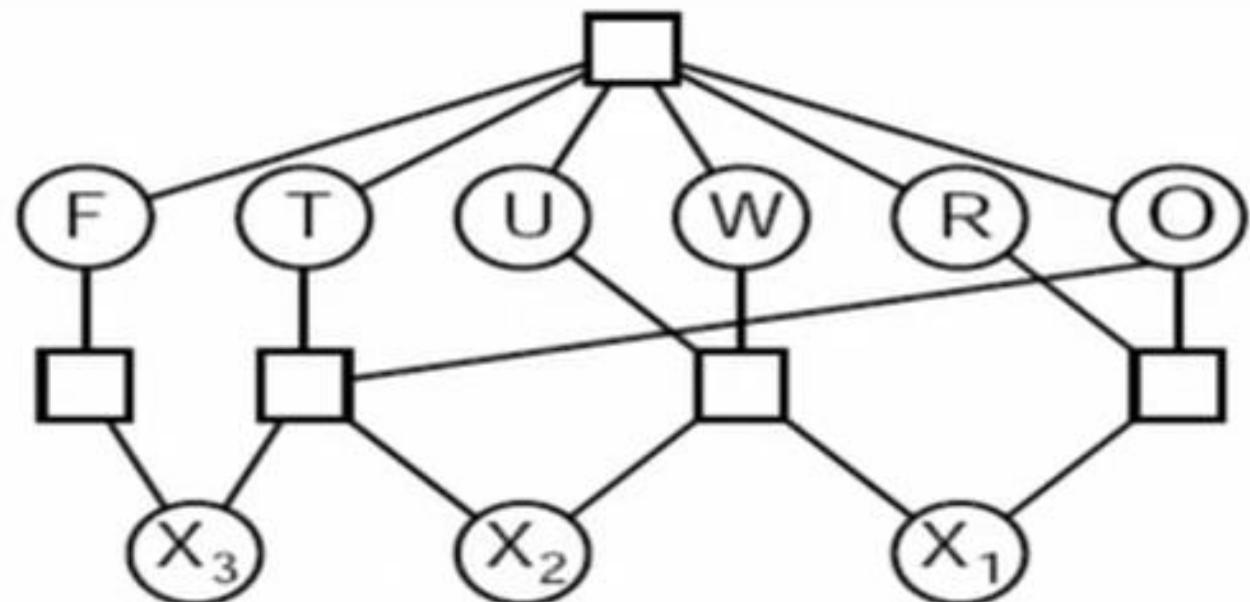

Preferences (soft constraints), e.g.,  $red$  is better than  $green$

often representable by a cost for each variable assignment

→ constrained optimization problems

## Example: Cryptarithmetic

$$\begin{array}{r} \text{T} \quad \text{W} \quad \text{O} \\ + \quad \text{T} \quad \text{W} \quad \text{O} \\ \hline \text{F} \quad \text{O} \quad \text{U} \quad \text{R} \end{array}$$

Variables:  $F \ T \ U \ W \ R \ O \ X_1 \ X_2 \ X_3$

Domains:  $\{0, 1, 2, 3, 4, 5, 6, 7, 8, 9\}$

Constraints

$allDiff(F, T, U, W, R, O)$

$O + O = R + 10 \cdot X_1$ , etc.
